Strongest delirium-associated contrast: days 0-30

Readmission and interaction

90-day same-system readmission

G1
25.2%

G2
27.5%

G3
26.9%

G4
27.5%

All exposed groups had modestly higher risk

No robust evidence of positive interaction

Early delirium was the dominant mortality marker

Early ICU delirium identified survivors with higher one-year mortality, especially within 30 days after discharge; psychiatric comorbidity added smaller risk and showed no robust positive interaction.
